

Current measurement: Shunt + Inst.Amp. + Selectors

Test Points & Mounting Holes

Measurement Considerations

The on-board ADC of the Pynq Z2 board has a reference voltage of 1.0 V
Signals can be digitized in two ways:

- Through the arduino-compatible pins A0–A5,
- Through the VP pin on the vertical female connector adjacent to the buttons.

The arduino-compatible pins are internally connected to a resistor voltage divider that outputs 1.0 V when the input voltage is 3.3 V.
The VP pins are directly connected to the ADC input.

Thus, the range of the Arduino-pins is higher at a cost of their resolution.

To toggle between the two inputs, use the SW2 (ANA) switch (Left VP – Right Arduino A0 Pin)

The amplifier has a gain of 100 V/V, and the shunt resistor is 8 mΩ.
Thus $V_{ADC} = (I_{LOAD} * R_{SHUNT}) * 100$

Taking this into account, for the VP pin, we have that saturation ($V_{ADC} = 1.0$ V), will be reached when $I_{LOAD} = 1.25$ A.
If currents greater than 1.25 A are required (to power external PMODs, for instance), the switch should be set to A0.

The obtained resolution is:

- 0.3 mA for VP
- 1.0 mA for A0
